Question 1 Correct Mark 10.00 out of 10.00

if and else are two of the most frequently used conditionals in C/C++, and they enable you to execute zero or one conditional statement among many such dependent conditional statements. We use them in the following ways:

1. if: This executes the body of bracketed code starting with **statement1** if **condition** evaluates to true.

```
if (condition) {
    statement1;
    ...
}
```

2. *if* - *else*: This executes the body of bracketed code starting with *statement1* if *condition* evaluates to *true*, or it executes the body of code starting with *statement2* if *condition* evaluates to *false*. Note that only *one* of the bracketed code sections will ever be executed.

```
if (condition) {
    statement1;
    ...
}
else {
    statement2;
    ...
}
```

3. *if - else if - else:* In this structure, dependent statements are chained together and the *condition* for each statement is only checked if all prior conditions in the chain evaluated to *false*. Once a *condition* evaluates to *true*, the bracketed code associated with that statement is executed and the program then skips to the end of the chain of statements and continues executing. If each *condition* in the chain evaluates to false, then the body of bracketed code in the *else* block at the end is executed.

```
if(first condition) {
    ...
}
else if(second condition) {
    ...
}
.
else if((n-1)'th condition) {
    ....
}
else {
    ...
}
```

Given a positive integer n, do the following:

- If $1 \le n \le 9$, print the lowercase English word corresponding to the number (e.g., one for 1, two for 2, etc.).
- If n > 9, print Greater than 9.

Input Format

A single integer, n.

Constraints

• $1 \le n \le 10^9$

Output Format

If $1 \le n \le 9$, then print the lowercase English word corresponding to the number (e.g., one for 1, two for 2, etc.); otherwise, print Greater than 9.

Sample Input 0

5

Sample Output 0

five

Explanation 0

five is the English word for the number 5.

Sample Input 1

8

Sample Output 1

eight

Explanation 1

eight is the English word for the number 8.

Sample Input 2

44

Sample Output 2

Greater than 9

Explanation 2

n=44 is greater than 9, so we print Greater than 9.

For example:

Input	Result
5	five
8	eight
44	Greater than 9

Answer: (penalty regime: 0 %)

```
25
                  case 3:
                       cout<<"three";</pre>
26
27
                       break;
28
                  case 4:
29
                       cout<<"four";
30
                       break;
                  case 5:
31
                       cout<<"five";</pre>
32
33
                       break;
34
                  case 6:
                       cout<<"six";</pre>
35
36
                       break;
37
                  case 7:
                       cout<<"seven";</pre>
38
39
                       break;
40
                  case 8:
41
                       cout<<"eight";</pre>
42
                       break;
43
                  case 9:
44
                       cout<<"nine";</pre>
45
                       break;
              }
46
47
         }
48 ,
         else{
              cout<<"Greater than 9";//when grater than 9</pre>
49
50
51
52

Marks for this submission: 10.00/10.00.

Question 2

Correct

Mark 10.00 out of 10.00

A for loop is a programming language statement which allows code to be repeatedly executed.

The syntax is

```
for ( <expression_1> ; <expression_2> ; <expression_3> )
     <statement>
```

- expression_1 is used for initializing variables which are generally used for controlling the terminating flag for the loop.
- expression_2 is used to check for the terminating condition. If this evaluates to false, then the loop is terminated.
- expression_3 is generally used to update the flags/variables.

A sample loop is

```
for(int i = 0; i < 10; i++) {
...
}
```

In this challenge, you will use a for loop to increment a variable through a range.

Input Format

You will be given two positive integers, a and b ($a \leq b$), separated by a newline.

Output Format

For each integer n in the inclusive interval [a, b]:

- If $1 \le n \le 9$, then print the English representation of it in lowercase. That is "one" for 1, "two" for 2, and so on.
- Else if n > 9 and it is an even number, then print "even".
- Else if n > 9 and it is an odd number, then print "odd".

Note:
$$[a,b]=\{x\in\mathbb{Z}\mid a\leq x\leq b\}=\{a,\ a+1,\ldots,b\}$$

Sample Input

```
8
11
```

Sample Output

```
eight
nine
even
odd
```

For example:

Input	Result
8	eight
11	nine
	even
	odd

Answer: (penalty regime: 0 %)

```
#include <iostream>
#include <cstdio>
using namespace std;

int main() {
    int a,b;
    cin>>a>>b;

for (int i=a;i<=b;i++){
    //printing name of number when number is lower than 9</pre>
```

```
if (1<=i && i<=9){
11 •
12 •
                  switch(i){
13
                       case 1:
14
                           cout<<"one\n";</pre>
15
                           break;
                       case 2:
16
                           cout<<"two\n";</pre>
17
18
                           break;
19
                       case 3:
                           cout<<"three\n";</pre>
20
21
                           break;
22
                       case 4:
23
                           cout<<"four\n";</pre>
24
                           break;
25
                       case 5:
                           cout<<"five\n";</pre>
26
27
                           break;
28
                       case 6:

Correct

Marks for this submission: 10.00/10.00.

1.

Question 3

Correct

Mark 10.00 out of 10.00

Objective

In this challenge, we practice reading input from stdin and printing output to stdout.

In C++, you can read a single whitespace-separated token of input using <u>cin</u>, and print output to stdout using <u>cout</u>. For example, let's say we declare the following variables:

```
string s; int n;
```

and we want to use cin to read the input "High 5" from stdin. We can do this with the following code:

```
cin >> s >> n;
```

This reads the first word ("High") from stdin and saves it as string s, then reads the second word ("t") from stdin and saves it as integer t. If we want to print these values to stdout, separated by a space, we write the following code:

```
cout << s << " " << n << endl;
```

This code prints the contents of string s, a single space (n), then the integer n. We end our line of output with a newline using n. This results in the following output:

High 5

Task

Read 3 numbers from stdin and print their sum to stdout.

Input Format

One line that contains ${\bf 3}$ space-separated integers: ${\bf a}$, ${\bf b}$, and ${\bf c}$.

Constraints

• $1 \le a, b, c \le 1000$

Output Format

Print the sum of the three numbers on a single line.

Sample Input

1 2 7

Sample Output

10

Explanation

The sum of the three numbers is 1 + 2 + 7 = 10.

For example:

Input	Result
1 2 7	10

Answer: (penalty regime: 0 %)

```
1 #include <cmath>
2 #include <cstdio>
3 #include <vector>
4 #include <ioostream>
5 #include <algorithm>
using namespace std;
7
```

```
9 v int main() {
    int a,b,c;//defining variables
    cin>>a>>b>>c;//getting inputs
    cout<<a+b+c;//printing the sum
    return 0;
}
</pre>
```

		Input	Expected	Got	
•	/	1 2 7	10	10	~

1.

Question 4

Correct

Mark 10.00 out of 10.00

Sorting

One common task for computers is to sort data. For example, people might want to see all their files on a computer sorted by size. Since sorting is a simple problem with many different possible solutions, it is often used to introduce the study of algorithms.

Insertion Sort

These challenges will cover Insertion Sort, a simple and intuitive sorting algorithm. We will first start with a nearly sorted list.

Insert element into sorted list

Given a sorted list with an unsorted number e in the rightmost cell, can you write some simple code to insert e into the array so that it remains sorted?

Since this is a learning exercise, it won't be the most efficient way of performing the insertion. It will instead demonstrate the brute-force method in detail

Assume you are given the array arr = [1, 2, 4, 5, 3] indexed $0 \dots 4$. Store the value of arr[4]. Now test lower index values successively from 3 to 0 until you reach a value that is lower than arr[4], at arr[1] in this case. Each time your test fails, copy the value at the lower index to the current index and print your array. When the next lower indexed value is smaller than arr[4], insert the stored value at the current index and print the entire array.

Example

n = 5

$$arr = [1, 2, 4, 5, 3]$$

Start at the rightmost index. Store the value of arr[4] = 3. Compare this to each element to the left until a smaller value is reached. Here are the results as described:

```
1 2 4 5 5
1 2 4 4 5
1 2 3 4 5
```

Function Description

Complete the insertionSort1 function in the editor below.

insertionSort1 has the following parameter(s):

- n: an integer, the size of arr
- arr: an array of integers to sort

Returns

• None: Print the interim and final arrays, each on a new line. No return value is expected.

Input Format

The first line contains the integer n, the size of the array arr.

The next line contains n space-separated integers $arr[0] \dots arr[n-1]$.

Constraints

```
\begin{array}{l} 1 \leq n \leq 1000 \\ -10000 \leq arr[i] \leq 10000 \end{array}
```

Output Format

Print the array as a row of space-separated integers each time there is a shift or insertion.

Sample Input

```
5
2 4 6 8 3
```

Sample Output

```
2 4 6 8 8
2 4 6 6 8
2 4 4 6 8
2 3 4 6 8
```

Explanation

3 is removed from the end of the array.

In the 1^{st} line 8 > 3, so 8 is shifted one cell to the right.

In the 2^{nd} line 6 > 3, so 6 is shifted one cell to the right.

In the 3^{rd} line 4 > 3, so 4 is shifted one cell to the right.

In the 4^{th} line 2 < 3, so 3 is placed at position 1.

Next Challenge

In the next challenge, we will complete the insertion sort.

For example:

Input	Result
5	2 4 6 8 8
2 4 6 8 3	2 4 6 6 8
	2 4 4 6 8
	2 3 4 6 8

Answer: (penalty regime: 0 %)

```
#include <bits/stdc++.h>
2
    using namespace std;
3
    string ltrim(const string &);
5
6
    string rtrim(const string &);
7
    vector<string> split(const string &);
8
9
    ^{st} Complete the 'insertionSort1' function below.
10
11
12
     * The function accepts following parameters:
    * 1. INTEGER n
13
    * 2. INTEGER_ARRAY arr
14
15
16
17
   void insertionSort1(int n, vector<int> arr) {
18 •
        int j=n-1;//assigning the idex of the last element
19
20
        int key=arr[j];//assigning unsorted element
21
        int i=j-1;
        while(i>=0 && key<arr[i]){//checking the condition</pre>
22 •
23
            arr[i+1]=arr[i];
24
            i=i-1:
25
            //printing the array
26 •
            for (int k = 0; k < (n); k++){
27
                cout << arr[k]<<" ";
28
            }
29
            cout<<endl;</pre>
30
        //when found the numer which is lower than our key
31
        arr[i+1]=key;
32
33
        //printing the array
        for (int k = 0; k < (n); k++){
34
35
            cout << arr[k]<<" ";
36
        cout<<endl;
37
38
    }
